# Apply filters to SQL queries

## Project description

You are a security professional at a large organization. Part of your job is to investigate security issues to help keep the system secure. You recently discovered some potential security issues that involve login attempts and employee machines.

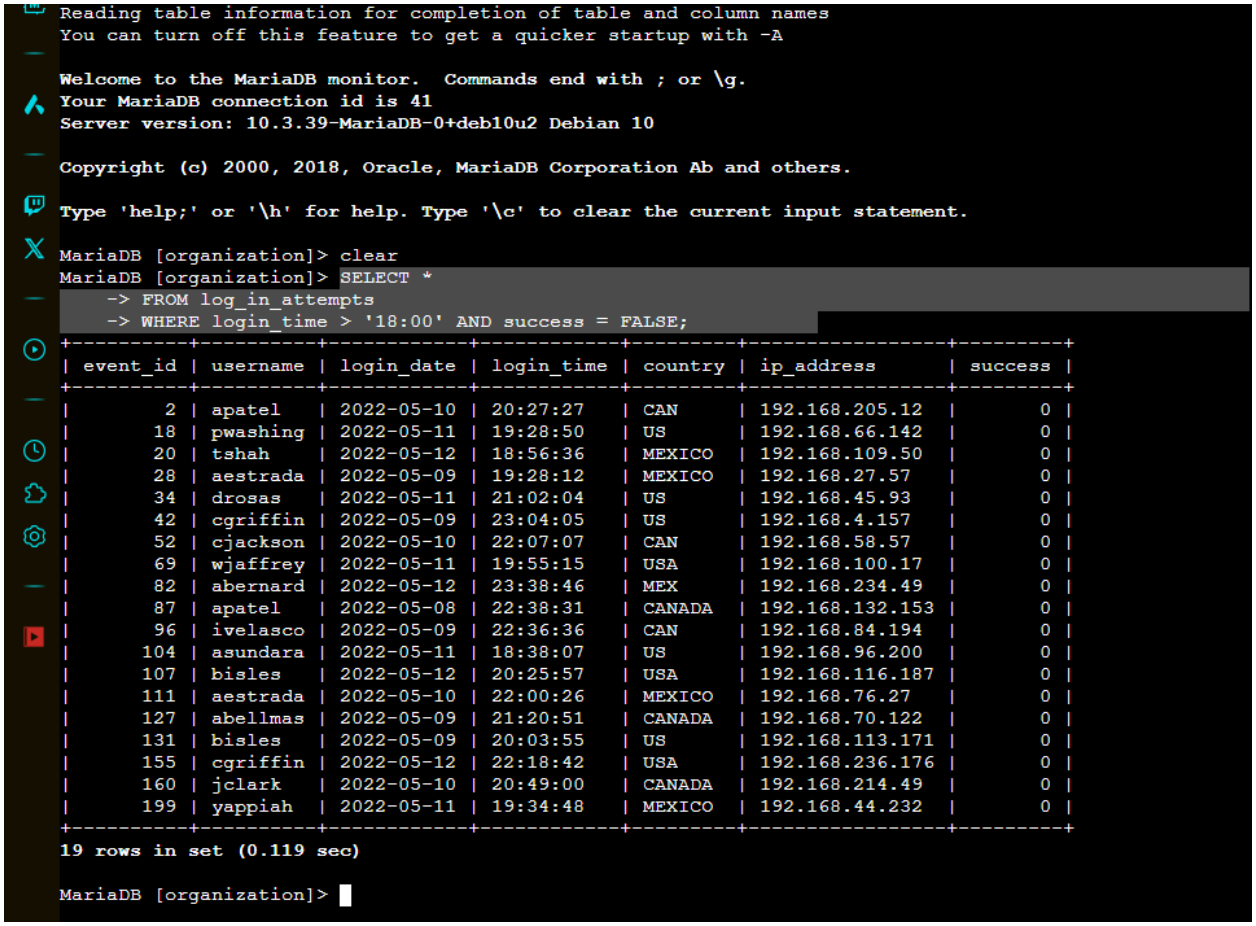
Your task is to examine the organization's data in their employees and log_in_attempts tables. You'll need to use SQL filters to retrieve records from different datasets and investigate the potential security issues.

## Retrieve after hours failed login attempts

We need to retrieve all failed login attempts that occurred after the office's hours. Since it closes at 18:00 we need to query for all false attempts in the success category of the login attempts table. The query which will give us the result we need in SQL is:

```
SELECT *
-> FROM log_in_attempts
-> WHERE login_time > '18:00' AND success = FALSE;
```

By using the **asterisk** in **select**, we are asking for all the columns in the log_in_attempts table. **From** is the table which we are pulling our data from, which again is the log_in_attempts table. **Where** is followed by the argument login_time which indicates the column we want to filter, **>** represents all results after '18:00' which is our pattern, **AND** indicates we also need the following to go along with our filtered time, success is once again an argument that represents a column, and lastly, FALSE or alternatively 0 is the pattern we need to fulfill our query.



## Retrieve login attempts on specific dates

A suspicious event occurred on 2022-05-09. To investigate this event, we want to review all login attempts which occurred on this day and the day before. To do this, we'll use the following:

**SELECT ***
**-> FROM log_in_attempts**
**-> WHERE login_date = '2022-05-09' OR login_date = '2022-05-08';**

**Select *** once again pulls all the columns in the desired table. **From** is still the log_in_attempts table. **Where** is querying from the login_date column which is true for both terms here, '2022-05-09' is the date we want to investigate, the same being true for '2022-05-08', but because we want all attempts made on both days including any time(s) that may intersect between the two we use the '**or**' operator instead of and. It achieves exactly what we want, and now we have a baseline to analyze for any suspicious traffic that might have occurred on these days.

```
MariaDB [organization]> SELECT *
    -> FROM log_in_attempts
    -> WHERE login_date = '2022-05-09' OR login_date = '2022-05-08';

## Retrieve login attempts outside of Mexico

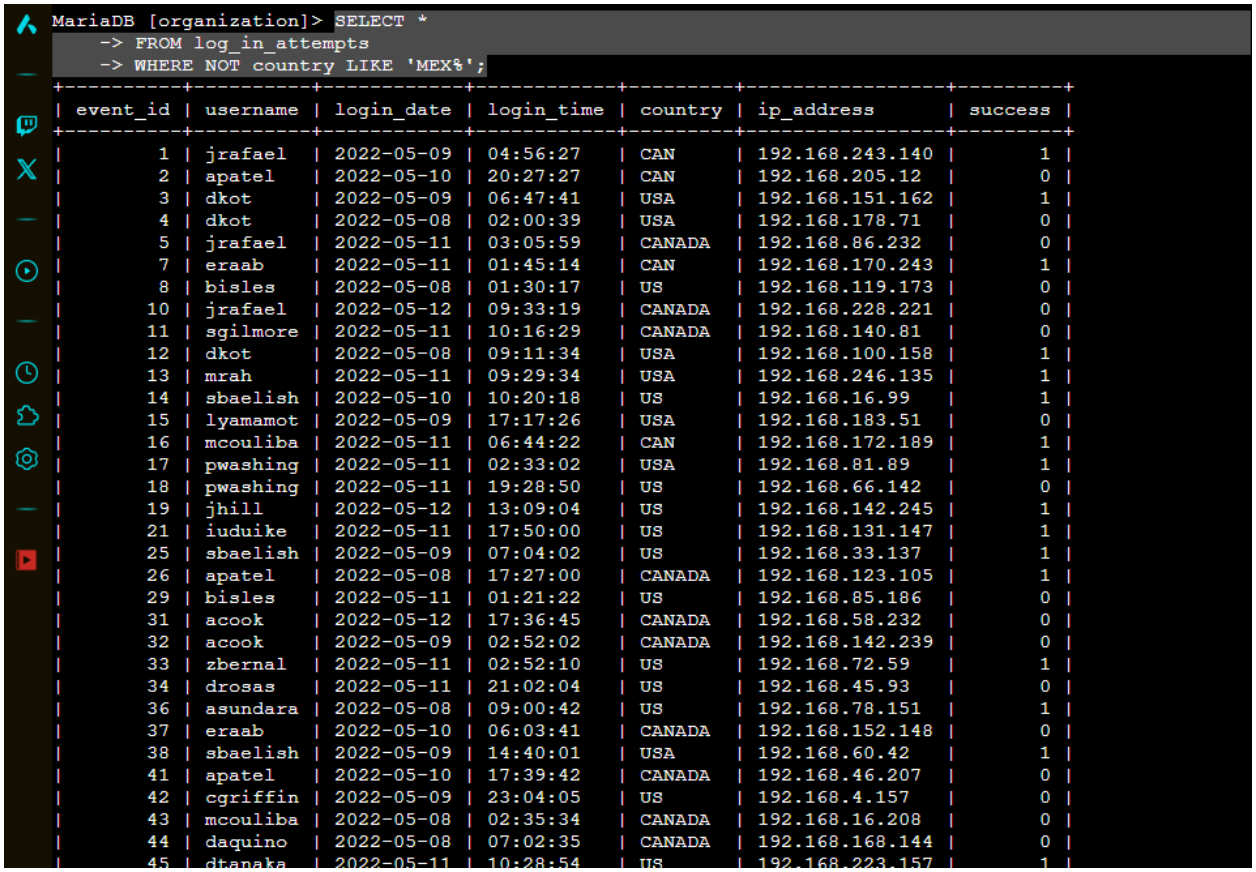
There's been suspicious activity with login attempts, but the team has determined that this activity didn't originate in Mexico. Now, we need to investigate login attempts that occurred outside of Mexico. The query which will give us the result we need in SQL is:

**SELECT ***

**-> FROM log_in_attempts**

**-> WHERE NOT country LIKE 'MEX%';**

Select and from are utilized the same as in the aforementioned sections above. Where is now followed by the '**not**' operator which is used to negate a result entirely. Since we want to look for login attempts outside of Mexico, we can eliminate it entirely with not, followed by the country column in the table, the operator '**like**' is used here for the **%** following MEX in the allocated pattern. Mexico might return as MEX or Mexico, so we use like and % to filter out all results that would start with MEX and anything beyond that such as the full spelling of Mexico instead of just the abbreviation.



```
MariaDB [organization]> SELECT *
    -> FROM log_in_attempts
    -> WHERE NOT country LIKE 'MEX%';
+----------+----------+------------+------------+---------+-----------------+---------+
| event_id | username | login_date | login_time | country | ip_address      | success |

## Retrieve employees in Marketing

Our team wants to perform security updates on specific employee machines in the Marketing department. We're responsible for getting information on these employee machines and we will now need to query the employees table. To do this, we'll use the following:

**SELECT ***

**-> FROM employees**

**-> WHERE department = 'Marketing' AND office Like 'East%';**

Select is the same, but now we're pulling data from the **employees table**. Since we're looking for specific employee machines in the marketing department, we've decided to look at all machines belonging to them in the east office(s). Where is followed by the department column which we want marketing for as our filter, '**and**' means we also want the filter from the office column which '**like**' is used in conjunction with **%** again to give us all the possible east office(s) instead of a singular result. Such as only filtering for those in East-170.

```
200 rows in set (0.005 sec)

MariaDB [organization]> SELECT *
    -> FROM employees
    -> WHERE department = 'Marketing' AND office Like 'East%';
+-------------+--------------+----------+------------+----------+
| employee_id | device_id    | username | department | office   |

## Retrieve employees in Finance or Sales

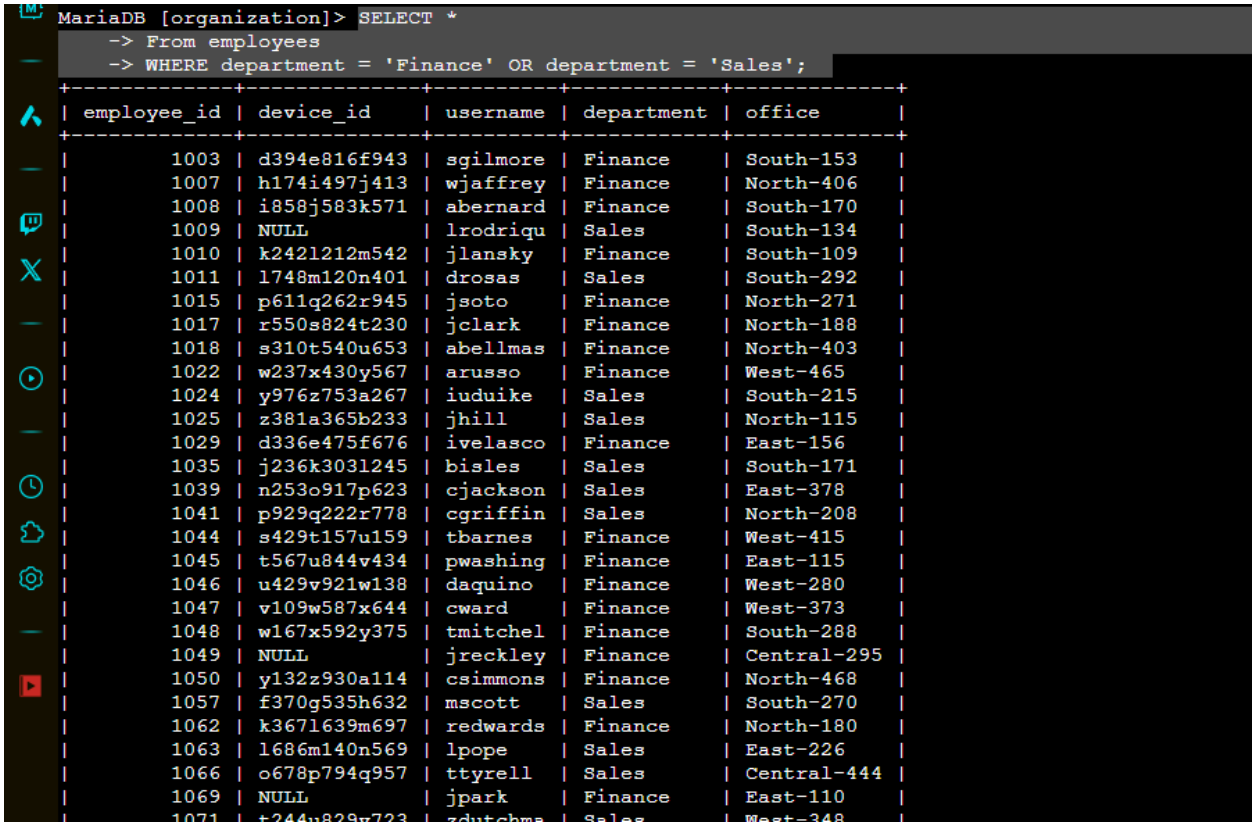
Our team now needs to perform a different security update on machines for employees in the Sales and Finance departments. The query which will give us the result we need in SQL is:

**SELECT ***

**-> From employees**

**-> WHERE department = 'Finance' OR department = 'Sales';**

Select and from remain the same here. Where is followed by the department column which is found in both of our filters, because we want all employees in the sales and finance departments we use the operator '**or**' to get all employees in either department and potentially any employees who work in both departments. This gives us the full range of machines we need to perform the different security update for.



```
MariaDB [organization]> SELECT *
    -> From employees
    -> WHERE department = 'Finance' OR department = 'Sales';
+-------------+-------------+----------+------------+-------------+
| employee_id | device_id   | username | department | office      |

## Retrieve all employees not in IT

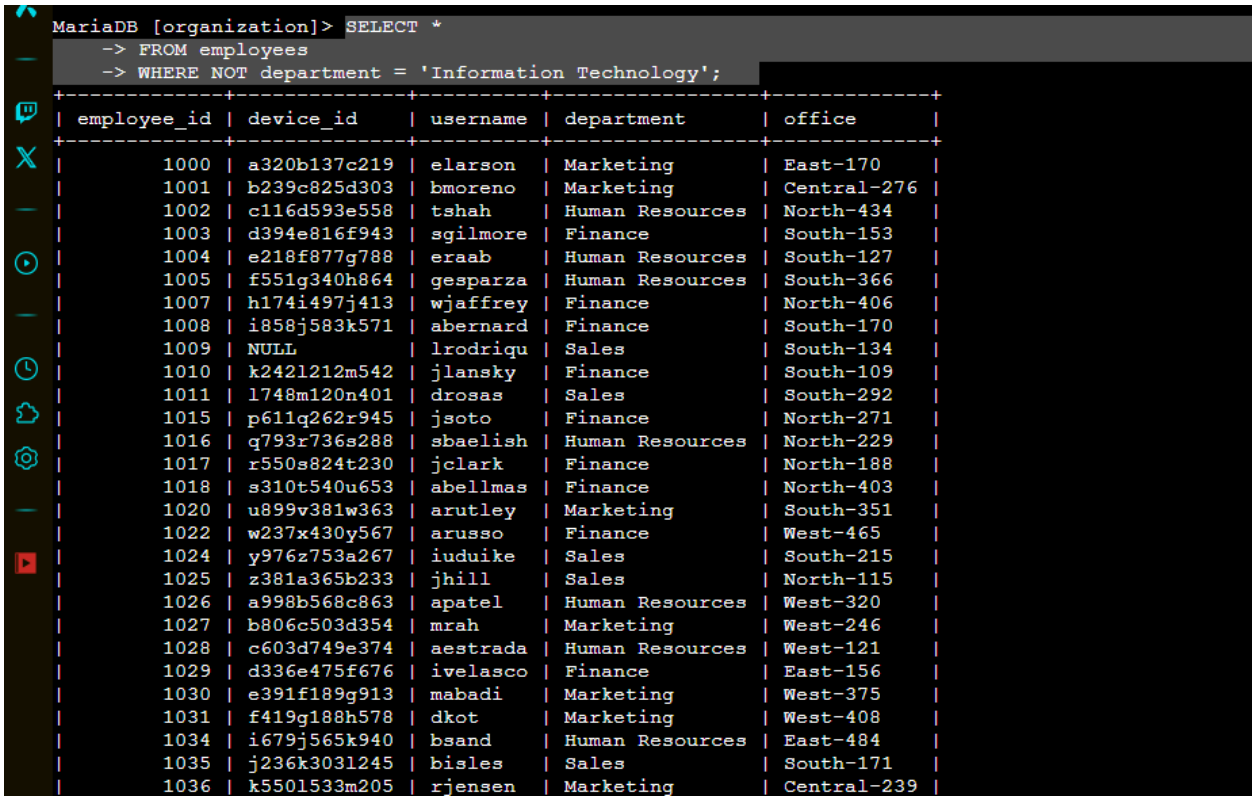
Our team needs to make one more update to employee machines. The employees who are in the Information Technology department already had this update, but employees in all other departments need it. To do this, we'll use the following:

**SELECT ***

**-> FROM employees**

**-> WHERE NOT department = 'Information Technology';**

Select for all columns, from the employees table. All machines that are not part of IT can easily be returned by omitting IT from the results, by using the '**not**' operator. By negating it with this query, we can see all other machines that belong outside of information technology and therefore providing us with which machines require this update.



```
MariaDB [organization]> SELECT *
    -> FROM employees
    -> WHERE NOT department = 'Information Technology';
+-------------+--------------+----------+-----------------+-------------+
| employee_id | device_id    | username | department      | office      |

## Summary

Querying in SQL allows us to quickly attain and analyze the data which is most pertinent to either a security event or to perform preventative security; both were put well on display here in our scenario. SQL promotes excellent time-management, saving analysts and other security members from agonizing over pouring through unfiltered logs, and goes hand-in-hand with boosting efficiency, allowing for a rapid response to security events.
